## INTRODUCTION

In this paper we are dealing with the estimation of the gravity-darkening exponent (GDE, $\boldsymbol{\beta}$ ), which describes the dependence of the emergent flux of total radiation on the local gravity acceleration of a rotationally or tidally distorted star in hydrostatic equilibrium. Theoretical predictions for stars with purely radiative energy transfer give the value of $\boldsymbol{\beta}=0.25$ [1], while for stars with convective envelopes $\boldsymbol{\beta}=0.08$ [2]. Recently however, it was suggested that both mechanisms could act simultaneously [3], and thus any value between these two extremes is expected.

Several attempts have been made to estimate the value of $\boldsymbol{\beta}$ from observational data for various kinds of binary systems (see e.g. [4] and references therein).

In a semi-detached binary system the secondary component fills its Roche lobe, while the primary is well deep inside its own Roche lobe. In the analysis of such a system it is reasonable to fix the GDE value of the primary star to its theoretical value. The appropriate GDE value for the Roche lobefilling component could be then empirically estimated from observational data by light-curve analysis.

## RESULTS

Here we have performed such an analysis on four semi-detached binary systems and estimated the GDE values for their Roche lobe filling components. More details on the applied model and method of light-curve analysis can be found in [4].

The binary systems in question are: $T W$ And (F0V + K1-3III-IV; P ~ $4^{\mathrm{d}} .12$ ) [5] with the mass ratio $\mathrm{q}=0.193$ estimated from radial-velocity measurements by [6]; TW Cas (B9 + G; P ~ $1^{\mathrm{d}} .428$ ) [7], [8] with $\mathrm{q}=0.38$ [9]; AI Dra (B9.6 V+ G2?; P ~ $1^{\mathrm{d}} .19 ; \mathrm{q}=0.43$ ) [10], and $U X \operatorname{Her}(\mathrm{~A} 2.6+\mathrm{K} ; \mathrm{P} \sim$ $1^{\mathrm{d}} .549 ; \mathrm{q}=0.248$ ) [11].

Tables 1 and 2 comprise the results of our light-curve analyses, and Fig. 1 and 2 give the graphic presentation of the obtained results. The subscripts (h,c) in the tables denote the hotter and cooler component of the system. The Note given below Table 1 is also valid for Table 2. For TW And, TW Cas, AI Dra and UX Her we have obtained $\beta_{\mathrm{c}} \sim 0.06, \beta_{\mathrm{c}} \sim 0.13, \beta_{\mathrm{c}} \sim 0.12$, and $\beta_{\mathrm{c}} \sim 0.06$, respectively. These values basically confirm theoretical predictions for stars with convective envelopes.

Table 2. Results from the analysis of AI Dra (Strömgren $y b v$ ) light curves, and UX Her (BV) light curves obtained by solving the inverse problem for the

Roche model. Gravity darkening exponent of the cooler secondary component ( $\boldsymbol{\beta}_{\boldsymbol{c}}$ ) was a free parameter.

Note: The labels are the same as in Table 1.

## DISCUSSION

The light-curve analysis of the four semi-detached binary systems ( $T W$ And, TW Cas, AI Dra, UX Her) presented here, made within the Roche model and gave us the real possibility to estimate the GDE values for their secondary components without any additional approximations. During the same analyzing procedure, we can estimate the systems' parameters, too, (as they are given at Tables $1 \& 2$ ). The estimated values of GDE basically confirm the theoretical predictions for stars with convective envelopes.
